Abstract: Influence of processing parameters on flexural properties of injection moulded polypropylene was investigated using response surface approach. Investigations were focused on the rheological behaviour of injection moulded polypropylene (PP) products at different temperature. Flexural strength test was conducted on the test specimens moulded at different injection temperatures ranging from 240°C to 280°C using polypropylene. The test information was analyzed statistical using design expert software version 10.1. The results obtained indicate that a melt temperature has an effect on viscosity of injection moulded polypropylene. Also, an optimum parameters and flexural strength values of 41.70°C, 239.19rpm, 227.34°C, 42.43s and 28.99MPa for mould temperature, screw speed, barrel temperature, cooling time and flexural strength respectively was obtained. The results of this finding will be useful in polymer industries were polypropylene is been used as a raw material during injection moulding were flexural strength is paramount.

Keywords: Influence, Parameters, Flexural, Injection Mould, polypropylene

I. INTRODUCTION

Polypropylene (pp) is a low – Cost polymer with versatile applications but with limited impact strength. In recent years, polymeric composites were widely used in the production of new engineering materials (Bilewicz et al, 2006). It is perceived as a reflection of technological development meanwhile the polymeric composites are promising due to their economic versatile applicability and good mechanical properties (Bociaga and Jaruga, 2007). The global market for polypropylene had a volume of 45.1million tonnes, which led to a turnover of about 65billion (Subodh et al, 2016). Polymers may be injection moulded including thermoplastics, fiber reinforced thermoplastics, thermosetting plastics and elastomers. Critical to the adoption of this high volume, low cost process technology is the ability to consistently produce quality parts (Kavade and Kadam, 2012).

Injection moulded polymer is any shape produced by heating polymer granules or powder in a tube at high temperature to melt, pushed by a rotating thread into a mould
and allowed to cool and solidify to take mould shape and size (Kingsburg, 2014). This is done to overcome the decrease in shear rate of molten material during flow and solidification in mould due to increased viscosity. This process can be used to produce a wide variety of products such as bottle tops, children toys, vehicle interior components etc which makes it the most important plastic manufacturing process.

Moreover, the properties of injection moulded materials are significantly influenced by the injection moulding conditions regardless of the part design (Ranlusha et al., 2012). Two of the conditions that have a substantial influence on the behaviour of the polymer are the melt temperature and mould temperature. Melt temperature is the actual temperature of the polymer as it exits the nozzle and enters the mould. Similarly, the actual surface temperature of the mould cores and cavities are related but not necessarily the same as the temperature of the fluid passing through the channels in the mould. It is generally understood that the melt temperature also has influence on the final molecular weight of the polymer in the moulded part. Mould temperature has less obvious but often profound effect on final properties however it is an important factor in determining the degree of crystallinity in semi crystalline materials (Sepe, 2011).

Melting of plastic materials is a slow process and hence determines the rate of plastic processing (Shubbar and Sawsan, 2013). Severe limitations are imposed on attainable rates by the thermal and physical properties of the plastics.

The low thermal conductivity of plastics limits the rate of heat transfer and thermal degradation places low bounds on the temperature and time the plastic can be exposed (Ayache, 2006).

Shubbar and Sawsan (2013), studied injection temperature effects on the properties of high density polyethylene crates it was revealed that the crates produced at a temperature range of 260-280°C gave the best rheological and mechanical result. (Ranlusha et al, 2012) investigated the effect of moulding temperature on the properties of Polypropylene/HDPE/Clay/Glass fibre (G.F), using polypropylene and HDPE (PP+HDPE) as base matrix. Nano fillers such as nano kaolin clay and glass fibre (G.F) were incorporated in the polymer with different combinations: (PP + HDPE), (PP + HDPE + Clay), (PP + HDPE + G.F) and (PP + HDPE + Clay + G.F). These materials were all moulded at different temperature. The specimen from each of the compounds were tested for tensile, flexural and impact strength.

Flexural strength decreased with increase in temperature from 180°C to 200°C in PP + HDPE and PP + HDPE + Clay samples ranging response from 43.80N/mm² and 49.90N/mm² to 38.80N/mm² to 38.70N/mm² while in the the samples containing Glass Fibre and G.F + clay with optimum flexural strength of 47.40N/mm² and 49.40N/mm² respectively at 190°C then dropped at 200°C.

(Satoru et al, 2010) worked on improving the rigidity and impact strength of polypropylene (PP) compounds. Using polypropylene, the first groups of specimens were reinforced with granular state calcium carbonate, the second specimen group, reinforced with tabular shaped talcum and the third group was reinforced with needle shaped glass fiber, after which they were tested. Impact and flexural strength, according to their % wt and particle size. The result depicted higher impact strength for smaller particle size and 8.60J/m² at 4.00mm diameter then 3.60J/m² at diameter of 24.00mm.

The difficulty is further compounded by the very high viscosity of the molten plastic. This is because, melts (a solid material in molten form as a result of increase in temperature i.e. to melting point) are non-Newtonian fluids; therefore increase in viscosity decreases their shear rate resulting to reduced rheological flow The interior door opener and bumper of some automobiles are made of polypropylene the door opener need high flexural strength while the bumper needs more of impact strength. This work is geared towards reducing failure rate by providing information that will serve as a guideline to manufacturers in selecting processing Parameters with respect to expected property of component. Specifically, is to study the significance of the influence of injection moulding parameters on the flexural properties of polypropylene products.

II. MATERIALS AND METHOD

The plastic material used in this work is Polypropylene (PP). This was chosen because they are the most commonly used in manufacturing of components for mechanical devices, mostly used in interior parts of automobiles, aircrafts, ships automobile bumpers

Clamping force, \( F = 56.1\text{tons} \)

Barrel Temperature = 230°C

DESIGN OF EXPERIMENT FOR PROCESSING PARAMETER EFFECT ON FLEXURAL STRENGTH OF INJECTION MOULDED PP

Design Expert software (version 10.1) was used in this study to design the experiment and to optimize the reaction conditions. The experimental design employed in this work was a two-level-four factor fractional factorial design, including 30 experiments. Barrel temperature, Screw speed, Mould temperature and cooling time were selected as independent factors for the optimization study. The response chosen was the flexural strength of PP. Eight replications of centre points were used in order to predict a good estimation of errors. The experiments were performed in a randomized order. The actual and coded levels of each factor are shown in Table 1. The coded values were designated by \(-1\) (minimum), 0 (centre), +1 (maximum), \(-\alpha\) and +\(\alpha\). Alpha is defined as a distance from the centre point which can be either inside or outside the range, with the maximum value of 2n/4, where n is the number of factors (Vicente et. Al.). Hereby the value of alpha is set at 0.5. It is noteworthy to point out that the software uses the concept of the coded values for the investigation of the significant terms, thus equation in coded values is used to study the effect of the variables on the response. The empirical equation is represented as shown below:

\[
Y = \beta_0 + \sum_{i=1}^{4} \beta_i X_i + \sum_{i=1}^{4} \sum_{j=1}^{4} \beta_{ij} X_i X_j + \sum_{i=1}^{4} \sum_{j=1}^{4} \sum_{k=1}^{4} \beta_{ijk} X_i X_j X_k
\]

\[
Y = \frac{1}{2} \left( \sum_{i=1}^{4} \beta_i X_i + \sum_{i=1}^{4} \sum_{j=1}^{4} \beta_{ij} X_i X_j + \sum_{i=1}^{4} \sum_{j=1}^{4} \sum_{k=1}^{4} \beta_{ijk} X_i X_j X_k \right)
\]

\[
Y = \frac{1}{2} \left( \sum_{i=1}^{4} \beta_i X_i + \sum_{i=1}^{4} \sum_{j=1}^{4} \beta_{ij} X_i X_j + \sum_{i=1}^{4} \sum_{j=1}^{4} \sum_{k=1}^{4} \beta_{ijk} X_i X_j X_k \right)
\]
Selection of levels for each factor was based on the experiments performed to study the effects of process variables on the application of injection moulding for processing of PP. The lower extreme level of barrel temperature was 190°C since below that moulding was impossible as PP could not melt and the upper extreme level of temperature was 270°C. The levels of screw speed were selected between 229rpm and 249rpm, a range of 30°C and 50°C for mould temperature and the cooling time was limited between 33.1Secs and 53.1Secs (as obtained from WIBA Assist 10.1).

### A. DETERMINATION OF FLEXURAL STRENGTH

\[
EI = \frac{P^2l^4}{48} (\frac{1}{y})
\]

The deflection load, \( P = 1.0 \times 9.8 = 9.81 \)

Length of beam, \( L = 100\text{mm} \)

\[
\therefore \text{Flexural strength, } E' = \frac{9.81 \times 10^9 \times \left[ \frac{1}{48} \right]}{y}
\]

\[
= 204.3 \times \left[ \frac{1}{3} \right] \times 10^5 \text{Nm}^2
\]

\( Y = \text{Deflection} \)

### B. EXPERIMENTATION

Flexural test was carried out using Timus Olsen Universal Testing Machine in accordance with ASTM D790 (P=9.81N). The mandrel of 12mm for test fixed on the machine vice and the sample was placed on the machine vice and test commenced. As the Specimen is stretched the computer generated data was displayed on the monitor screen, the flexural test was performed at a speed of 100mm/min.

### III. RESULT AND DISCUSSION

The 3D response surface plots were generated to estimate the effect of the combinations of the independent variables on the flexural strength. The plots are shown in Figures 2 to 7.

### REFERENCES

[6] Kavade M. V. and S. D. Kadam (2012), *parameter optimization of injection molding of polypropylene by packing as more material is forced into the cooling melt in the cavity and this continues until the gate seals, leading to inhibited relaxation; thus molecular orientation increase thus increase in flexural strength as seen in figure 5. These factors usually combine with the degree of crystallization achieved during solidification to determine the solid properties, but if too high it leads to thermal degradation.

The extended cooling time will increase relaxation and hence decrease in grain orientation. This is illustrated in figures 7

### IV. CONCLUSIONS

From the foregoing, the following conclusions were drawn.

That the rate of heat transfers during melting and solidification both inside and outside the mould has a profound effect on the solid properties of plastics.

That the obtained optimum processing parameters and optimum flexural strength should be used in injection moulding where high flexural strength is needed.

Table 4: Results of the model validation (experiment indicates the optimum processing parameters and flexural strength)
